2.1 INTRODUCTION

As part of VISION 2050, the feedback obtained from the initial visioning activities (described in Chapter 1 of this volume) led into a scenario planning effort. Scenario planning was used to further develop a long-term shared vision by considering and evaluating a range of potential future scenarios of regional land use development and transportation system development. Developing and comparing possible scenarios, or futures, helped the public and local officials understand the consequences of future land use patterns and transportation systems and made it easier to provide input into the plan development process. The current Federal transportation bill, the Fixing America’s Surface Transportation Act (FAST Act), also suggests that metropolitan transportation planning organizations (MPOs) consider using scenario planning in developing regional transportation plans.

As mentioned in the previous chapter, the VISION 2050 Guiding Statements provided direction to the Commission staff in developing a series of conceptual land use and transportation scenarios and a series of criteria for comparing those scenarios. Scenarios are conceptual designs of alternative ways in which the Region could develop through the year 2050. The five scenarios developed by staff represent a range of possible futures for land use and transportation. These scenarios are intended to be “what if” illustrations, varying based on the location, density, and mix of new development and redevelopment, and transportation system development.

The conceptual scenarios include one that continues current trends—Scenario A—and four with different levels of investment in the transportation system and different development patterns. Those four scenarios were intended to represent alternative futures that could achieve the initial vision, generally described by the Guiding Statements, which were developed using the results
of the visioning activities conducted during the previous steps in the VISION 2050 process.

The Commission staff evaluated how each scenario would perform relative to the other scenarios. To evaluate and assist in comparing the scenarios, a series of 13 measurable criteria were selected. Values for each criterion were then estimated for each scenario, with the results presented in a “scenario scorecard” that allowed the scenarios to be easily compared in terms of their relative benefits, costs, and impacts.

The extensive public outreach and engagement conducted as part of each step in the VISION 2050 process continued with the scenarios. A third round of interactive public workshops was held across the Region, along with workshops held by each of the eight VISION 2050 partner organizations and additional workshops held by request. The Commission staff also developed an interactive online tool, allowing interested residents to explore and provide feedback on the scenarios and their evaluation (http://vision2050sewis.com/Vision2050/The-Process/Sketch-Scenarios). The feedback obtained during this step of the process was used to develop and evaluate more detailed alternative land use and transportation plans, which are described in Chapter 3 of this volume.

2.2 SCENARIO DEVELOPMENT PROCESS

The conceptual scenarios varied based on each scenario’s development pattern and the level and type of investment in the transportation system. The process for developing the land use and transportation components of each scenario is described below.

Developing the Land Use Component

Developing the land use component of each scenario involved the use of a scenario planning tool called CommunityViz. CommunityViz was used to create a conceptual land use model for allocating projected household and employment growth through the year 2050 across the Region. The first step was to gather baseline data for the CommunityViz land use model so that a trend scenario (Scenario A) could be developed. The primary baseline data, described in Chapters 2 and 6 in Volume I of this report, included:

- Year 2010 employment and households per U.S. Public Land Survey Quarter Section
- Existing land use (based on the Commission’s 2010 land use inventory)
- Planned land use from composite county comprehensive plan maps developed for the Commission’s year 2035 regional housing plan
- The Commission’s year 2050 household and employment forecasts for each county in the Region

Using these baseline data in the CommunityViz model, staff then determined restricted lands—those which would not receive any allocations of household or employment growth. Restricted lands included primary environmental corridors, wetlands, open water, floodplains, areas with steep slopes, public park and open space sites, farmland preservation areas identified in county farmland preservation plans, and certain major land uses that would prevent development on a particular parcel, such as General Mitchell International Airport.
After identifying the restricted lands, staff then estimated the total capacity of households and employment for each U.S. Public Land Survey quarter section of land in the Region. These capacities represented the maximum amount of households and jobs that could be present in each quarter section. Capacities in Scenario A were limited by the planned land uses in each community’s comprehensive plan, while the other scenarios made some limited exceptions to these planned capacities. These exceptions included increased capacities in areas targeted by communities for redevelopment under Scenarios B, C, D, and E, and increased capacities in areas within walking distance of a fixed-guideway transit station under Scenarios C, D, and E. These increased capacities allowed the model a reasonable amount of flexibility to allocate growth in the form of redevelopment and transit-oriented development. CommunityViz was then used to subtract the year 2010 employment and households from these total capacities to determine the net available capacity for development in each quarter section. These net capacities represented the maximum amount of incremental households and jobs—to be added between 2010 and 2050—that could be allocated to each quarter section under each scenario.

The incremental households and jobs that the model could allocate were then incorporated into the model for each scenario. For all five scenarios, the overall growth in the Region was constrained to the regional intermediate growth projections of about 172,300 additional households and about 210,300 additional jobs by the year 2050 (presented in Chapter 6 of Volume I of this report). For Scenarios A and B, the model allocated each county’s intermediate growth projection of households and jobs. For Scenarios C, D, and E, the model was required to allocate at least the low growth household and employment projections in each county. Tables 2.1 and 2.2 present the amount of incremental growth in households and employment for each county under each scenario.

With the above constraints in place, the model allocated the incremental households and jobs under each scenario using a number of suitability factors. These suitability factors represented a variety of attractors of development, and staff was able to change the weight of each factor based on the characteristics of each scenario. The suitability factors that were used are presented in Table 2.3.

Developing the Transportation System Component

Developing the transportation system component of each scenario involved identifying different ways of investing in transportation infrastructure and services, including the arterial street and highway system, the public transit system, and bicycle and pedestrian facilities. Each scenario’s transportation system was designed to serve and be consistent with the scenario’s land development pattern. The process began by reviewing the recent trends in transportation system development and the recommendations in the year 2035 regional transportation system plan. Staff then identified key concepts for each transportation system element that would be desirable to compare in the scenarios, and determined how each concept would vary between the scenarios.

In terms of the Region’s transit system, the scenarios differed with respect to the level and technology of transit facility and service investments. Scenario A assumed transit service reductions similar to recent trends, including consideration of the comparison of current and expected revenues to current and expected capital, operating, and maintenance costs for the Region’s existing transit services. Scenario B included a significant increase in transit services, similar to that recommended in year 2035 regional transportation plan, reversing the recent trend of declining service levels. The improvements were focused on expanding bus services—service to more areas, longer hours of service, and more frequent service—and establishing a system of express bus routes.

Transit improvements in Scenarios C, D, and E went beyond the significant increase to existing bus services under Scenario B. Scenario C included a system of rapid transit lines—light rail or bus rapid transit (BRT)—developed in the Milwaukee area, Scenario D included a system of commuter rail lines between the Region’s urban centers, and Scenario E included both a rapid transit system and a commuter rail system. The location of each rapid transit and commuter rail line was initially identified by reviewing the potential lines identified in the year 2035 regional transportation system plan. Staff then slightly modified the lines based on considerations such as existing and expected development patterns, socioeconomic characteristics, and the presence of activity centers. For the rapid transit lines, the technology—light rail or BRT—was not specified, with the understanding that the specific technology would be determined during a more detailed corridor study. The commuter rail lines generally followed existing or former freight railroad lines. Table 2.4 presents the service headways and hours of service for the transit services included in each scenario.

For bicycle and pedestrian facilities, the trend in providing facilities has been greatly affected by Federal and State requirements that bicycle and pedestrian accommodations be provided in all new highway construction and reconstruction projects funded with State or Federal funds, unless demonstrated to be prohibitive. The off-street network has also been expanding. To explore different levels of bicycle investment, staff proposed under Scenarios A and B, the continuation of the trend of an expanding off-street network, and implementation of basic bicycle facilities as the arterial street and highway system is reconstructed. Scenarios C, D, and E also included the off-street bicycle path network, but went beyond the basic required on-street bicycle facilities to include higher levels of bicycle accommodation, such as protected bicycle lanes in key bicycle corridors. For pedestrian accommodations, all five scenarios assumed pedestrian facilities designed and constructed consistent with Americans with Disabilities Act (ADA) requirements, thus accommodating people with disabilities. Where

they varied was in the connectivity of sidewalks based on each scenario’s
general development pattern.

For the Region’s arterial street and highway system, it was recognized
that a significant portion of the Region’s major roads—including freeways,
State highways, county highways, and major local streets—will need to be
reconstructed between now and 2050. A recurring comment during the initial
visioning activities, at least in some parts of the Region, was that highway
capacity expansion should be limited. One of the concepts focused on in
the scenarios, therefore, was whether or not the arterial street and highway
system included capacity expansion in the form of additional traffic lanes
and new facilities. Highway capacity additions were included in Scenarios A
and B. These capacity additions would address the residual traffic congestion
that may not be alleviated by transit, bicycle, and other measures. For
Scenarios C, D, and E, highway improvement was proposed to be limited
to modernization to current safety and design standards as highways are
reconstructed.

Staff recognized that certain arterial highway capacity improvement and
expansion projects had already been committed and such projects were
included in all five scenarios. These projects were either under construction,
were undergoing final engineering and design, or had a preferred alternative
selected as part of preliminary engineering and environmental impact study.
Table 2.5 and Map 2.1 present the projects that were considered to be
committed at the time the scenarios were developed.

2.3 DESCRIPTION OF CONCEPTUAL SCENARIOS

As noted previously, five conceptual land use and transportation scenarios
were developed during this step in the VISION 2050 process. They included
four scenarios representing alternative futures that, to varying extents, could
achieve the initial vision, along with one scenario that assumed a continuation
of current trends in land and transportation system development. The five
scenarios and the basic concepts that varied between them are presented in
Table 2.6 and are described below.

Development Patterns Under the Scenarios
A primary way in which the five scenarios differed was the development
pattern under each scenario, including the location, density, and mix of new
development and redevelopment. As discussed previously in the chapter, the
land use component of each scenario was developed using a sketch land use
model that allocated incremental growth in households and employment
based on the weighting of a series of suitability factors. By modifying the
weighting of each suitability factor for each scenario, the model predicted
where the incremental growth would occur, essentially producing each
scenario’s development pattern. The household growth that would be
expected by the year 2050 under each scenario is presented on Maps 2.2A
through 2.2E. The employment growth that would be expected by the year
2050 under each scenario is presented on Maps 2.3A through 2.3E.

Scenario A represented a continuation of recent trends in land and
transportation system development in the Region from the past approximately
20 years. Most growth under Scenario A would occur in and around existing
cities and villages, with single-family development within urban service
areas at the edges of cities and villages on larger lots than the other four
scenarios. Urban service areas generally include cities and villages and the
immediate surrounding area where future growth is anticipated. These areas

The reconstruction of IH 94 between 70th Street and 16th Street is not included as the project had not progressed to that stage.

Source: SEWRPC

New development under Scenario B would be more compact than Scenario A.

New development under Scenario B would be more compact than Scenario A. There would also be more growth in Scenario A outside urban service areas at lower densities than the other four scenarios. Most of the growth outside urban service areas would be a scattering of new homes built on large lots of 1.5 or more acres in size. These homes would have private onsite water supply and wastewater treatment systems.

New development in Scenario B would mostly occur as redevelopment or infill in existing urban areas or immediately around existing cities and villages within their urban service areas, with residential growth being more compact.

and on smaller lots than under Scenario A. Residential densities would be higher than in Scenario A, resulting in a reversal of declining urban density. The focus of development and redevelopment would be in the larger urban core areas and other city and village urban service areas throughout the Region. Significantly more new homes would be built in urban service areas and would be served with public water and sewer. Single-family development within urban service areas at the edges of cities and villages would be on smaller lots than Scenario A (about one-quarter acre lots compared to one-half acre lots in Scenario A). The loss of farmland would largely be limited to the edges of existing cities and villages. It would also result in a mix of housing types in some areas that could include not only single-family homes, but also duplexes and apartments. The development of neighborhoods with a mix of uses, such as housing, businesses, schools, and parks, would occur.

The focus of new development under Scenarios C, D, and E would take the form of compact clusters around fixed-guideway transit stations (light rail, BRT, or commuter rail), with the type of transit stations depending on the scenario. This type of development is often referred to as transit-oriented development (TOD). TOD refers to compact, mixed-use development located near a transit station, with streets and sidewalks that provide convenient access for walking and bicycling to the station. It is widely accepted that a higher level of transit service—such as light rail, BRT, and commuter rail—is needed to develop a TOD. Investment in residential, office, and retail development has been linked to investment in higher levels of transit service.

Bus service over existing streets and highways does not provide a long-term service commitment, and therefore, is less likely to result in investment in land development and redevelopment around its stops. Figure 2.1 highlights the benefits and challenges associated with TOD as well as a series of examples of existing TODs in the United States.

Under Scenario C, the TODs would be focused around rapid transit (light rail or BRT) stations. They would mostly be achieved through redevelopment and infill and would be focused in the Milwaukee area. However, additional compact, mixed-use development would also occur under this scenario. This development would primarily be through redevelopment and infill in, as well as development at the edges of, cities and villages outside Milwaukee. The residential development in these areas would include more smaller lot single-family homes and townhomes, and less large lot single-family homes. There may also be a mix of housing types within walking distance of other uses such as businesses, schools, and parks.

Similar to Scenario C, Scenario D emphasizes new development as compact TODs, but instead of being focused around rapid transit stations, the TODs would be focused around commuter rail stations. Commuter rail TODs located in the Milwaukee area would be similar in design to those under Scenario C, and would be achieved through redevelopment and infill. Unlike Scenario C, the commuter rail TODs in Scenario D would also occur in between larger urban areas in the Region, with those located outside the Milwaukee area also having a more compact, mixed-use, and pedestrian-friendly design. Given the nature of commuter rail service, significant commuter parking would likely be adjacent to some stations. As in Scenario C, additional redevelopment and infill would occur in cities and villages throughout the Region, along with development at the edges of cities and villages.

Scenario E would have the most compact development of the five conceptual scenarios. This scenario represents a combination of elements from Scenarios C and D, with mixed-use TODs around both rapid transit and commuter rail stations located outside the Milwaukee area. As in Scenarios C and D, in addition to the TODs, there would also be some redevelopment and infill away from rail stations in existing cities and villages under this scenario. This redevelopment and infill development could support a range of housing types and a mix of neighborhood uses such as businesses, parks, and schools. Some development would also occur at the edges of these cities and villages.

Healthy Community Concepts Under the Conceptual Scenarios
The “active transportation” component of future development, including bicycling and walking, also varied between the scenarios. Figure 2.2 provides an overview of the bicycle facility concepts that were considered while comparing the scenarios. Figure 2.3 provides an overview of the pedestrian concepts that were considered while comparing the scenarios.

As mentioned previously in this chapter, the trend in providing bicycle and pedestrian facilities has been greatly affected by Federal and State requirements that bicycle and pedestrian accommodations be provided in all new highway construction and reconstruction projects funded with State or Federal funds, unless demonstrated to be prohibitive. The off-street network has also been expanding. In addition, ADA requirements need to be followed when designing and constructing pedestrian facilities to accommodate people with disabilities. All of this was assumed to continue through the year 2050 under all five scenarios.
Figure 2.1
Description of Transit-Oriented Development (TOD)

What is TOD?
- Compact, mixed-use development located near a transit station with streets and sidewalks that provide convenient access for walking and bicycling to the station.
- Investment in residential, office, and retail development has been linked to investment in higher levels of transit service, such as light rail, bus rapid transit, and commuter rail.

Benefits of TOD
- Can reduce transportation costs for residents by encouraging transit ridership
- Can be a catalyst for redevelopment and increase property value and tax revenues
- Increases foot traffic for local businesses

Challenges of TOD
- May require land assembly
- May face community opposition to increased density
- Increase in land prices may raise housing costs and reduce affordability
Federal and State regulations now require bicycle accommodations to be included in all new highway construction and reconstruction projects funded with State or Federal funds, unless demonstrated to be prohibitive. The typical on-street bike facilities in the Region are either unprotected bike lanes or paved shoulders.

Higher levels of accommodation—including Scenarios C, D, and E—like buffered and protected bike lanes can create defined space between bikes and motorized traffic and improve safety. Bike boxes and colored pavement can further define travel space and improve visibility of bicyclists in mixed-traffic.

Local streets experiencing through traffic can be designed as bicycle boulevards, with traffic calming measures used to discourage motorized traffic and prioritize bicycle traffic. Bicycle boulevards can help create continuous routes where bicyclists can safely travel through urban areas and connect neighborhoods.

Off-street paths connect urban areas and communities in the Region and provide routes separated from motorized traffic. These bicycle paths provide both opportunities for active recreation and a well-connected network that can provide a viable alternative to the automobile. Filling gaps in the trail network and ensuring proper maintenance can encourage more non-recreation bicycle travel.
Figure 2.3
Description of Pedestrian Concepts Under the Conceptual Scenarios

Connectivity/Walkability
Connectivity is having direct links that connect people to other homes in their neighborhood, shopping, schools, parks, and other destinations. Walkability is the ease by which people can walk to various destinations in an area.

Considerations include:
- Sidewalks and paths in a neighborhood
- Directness and distance of routes
- Land use mix and density
- Road network design

Improved connectivity and walkability can:
- Encourage more walking trips
- Reduce the need to make vehicle trips
- Make it easier to walk within a neighborhood

Accessibility
Accessibility is the ability to reach a destination without difficulty.

Considerations include:
- Street Width
- Treatment of Obstructions
- Intersection Markings
- Access to Transit
- Separation
- Visibility

Pedestrian facilities must also be designed and constructed consistent with Americans with Disabilities Act (ADA) requirements to accommodate people with disabilities.

Credit: (row 1) FHWA; SEWRPC; (row 2) Google Maps Street View; FHWA; (row 3) SEWRPC; SEWRPC; (row 4) Google Maps Street View; Christopher Andrews; (row 5) U.S. Department of Justice; Charlotte Department of Transportation
Reflecting recent regional trends in bicycle accommodations, Scenario A anticipated basic bicycle facilities—bike lanes, wider curb lanes, or paved shoulders—would be provided as non-freeway major roads are reconstructed, with off-street facilities also added to provide a well-connected off-street network. Pedestrian facilities would be designed and constructed consistent with ADA requirements; however, due to the trend in lower-density development, the connectivity of sidewalks would be limited in many areas of the Region.

Scenario B assumed similar provision of on-street and off-street bicycle facilities, and ADA-adherent pedestrian facilities. The difference between Scenarios A and B was that Scenario B would include a more compact development pattern, with limited lower-density development. This would likely result in more sidewalk connectivity than under Scenario A.

Scenarios C, D, and E assumed higher levels of bicycle accommodation—such as protected bicycle lanes—would be provided in key bicycle corridors. These higher levels of accommodation (described in Figure 2.2) would go beyond the minimum on-street bicycle facilities required to be provided as part of major road reconstruction projects. The scenarios also included the network of off-street bicycle paths under Scenarios A and B. Better sidewalk connections would also be anticipated under Scenarios C, D, and E as convenient walking access to transit stations is a focus of a compact TOD.

**Transportation System Investment Under the Conceptual Scenarios**

Another significant concept varying from scenario-to-scenario was the investment in major transportation system infrastructure and services, including the public transit system and the arterial street and highway system. Exploring different ways of investing in these elements of the transportation system was a major focus of the scenarios. As discussed previously in the chapter, each scenario’s transportation system was designed to serve and be consistent with the scenario’s land development pattern.

**Public Transit**

Since the early 2000s, transit service in the Region has declined nearly 25 percent. Under Scenario A, the already reduced transit service levels would be reduced by an additional 25 percent. This would particularly affect local bus service, resulting in entire routes being cut, lower service frequencies, reduced service hours, and/or weekend service being eliminated, depending on the transit system. Existing express bus service would be eliminated as well. Passenger fares would increase faster than inflation as transit systems attempt to maintain service levels as high as possible. Existing shared-ride taxi services would continue to operate, but no new shared-ride taxi services would be established.

Scenario B assumed a significant increase in existing bus transit services, reversing the trend of declining service levels that has occurred since the early 2000s. The increased transit services would continue to be provided primarily by buses. Increases would be in the form of improved and expanded local bus service—including service to more areas, longer hours of service, and more frequent service. Similarly, the existing commuter bus system would be improved and expanded, including initiating reverse commute service. A system of express bus routes would also be established. Shared-ride taxi services would be provided throughout the Region outside fixed-route bus service areas, with a 24-hour notice needed to schedule a ride.

Scenarios C, D, and E included fixed-guideway transit systems in addition to the significant increase to existing bus services under Scenario B. Figure 2.4 discusses
Traveling on improved freight corridors, Commuter Rail provides stops every 2 to 5 miles, service in both directions every 15 to 60 minutes, and stations with passenger amenities. Commuter Rail is included in Scenarios D and E.

Similar to Light Rail, Bus Rapid Transit (BRT) could be used to provide service in the Rapid Transit Corridors identified in Scenarios C and E. BRT operates in the median of a roadway or in a dedicated lane with stops every half mile to one mile, service every 5 to 15 minutes, priority at traffic signals, and stations with passenger amenities. It is intended to offer “rail-like” service with the potential for lower construction costs than Light Rail.
the different types of fixed-guideway transit technologies considered under these three scenarios. All three scenarios would include express and commuter bus routes. Similar to Scenario B, regionwide shared-ride taxi services would be provided outside fixed-route bus service areas, but the advance reservation requirement would be four hours instead of 24 hours.

Under Scenario C, a system of rapid transit lines within urban centers would be developed beyond the significant increase to existing bus services under Scenario B. Each light rail or BRT line would have its own lane or right-of-way, and would provide faster, more frequent (every 5 to 15 minutes) service than a standard local bus route. BRT lines would typically be located in long, straight, and wide corridors, with light rail lines typically located in corridors with higher-density development.

Scenario D would involve development of a system of commuter rail lines between urban centers. Each commuter rail line would use an existing or former freight rail corridor. Stations would be spaced every 2 to 5 miles, with trains running every 15 to 60 minutes depending on time of day.

Under Scenario E, both the rapid transit system from Scenario C and the commuter rail system from Scenario D would be developed. The rapid transit system would have the same characteristics as the system in Scenario C, while the commuter rail system would have the same characteristics as the system in Scenario D.

The quality of transit services in the Region in the year 2050 under each scenario is presented on Maps 2.4A through 2.4E. These maps also show the rapid transit corridors in Scenarios C and E, and commuter rail corridors in Scenarios D and E.

**Arterial Street and Highway System**

Each scenario recognized that a significant portion of the Region’s arterial street and highway system will need to be reconstructed between now and 2050. The primary difference between the scenarios was whether the arterial street and highway system included additional traffic lanes and new facilities, or was limited to modernizing the existing streets and highways to achieve current safety and design standards. Figure 2.5 provides an overview of the arterial street and highway system concepts considered under the scenarios.

Scenarios A and B would include additional traffic lanes as arterial streets and highways are reconstructed, and the construction of new facilities on the arterial street and highway system. The highway capacity additions under these two scenarios would be implemented only to address the residual traffic congestion that may not be alleviated by transit, bicycle, and other measures. Each reconstructed street and highway would also be modernized to achieve current safety and design standards.

Scenarios C, D, and E would not include additional traffic lanes as arterial streets and highways are reconstructed, or any new facilities, other than those considered as already being committed. As such, the highway improvements under these three scenarios would be limited to modernization to current safety and design standards as highways are reconstructed. These three scenarios would, therefore, not address residual traffic congestion after transit, bicycle, and other measures are implemented.

2.4 SKETCH EVALUATION OF CONCEPTUAL SCENARIOS

Public engagement related to the conceptual scenarios provided the first opportunity in the VISION 2050 process for residents to compare the long-term consequences of alternative futures. During each interactive workshop and through an online scenario exploration tool, residents were encouraged to consider these consequences, which were represented by sketch-level estimates for a series of evaluation criteria. Given the conceptual nature of the scenarios, the evaluation was not as in-depth as that conducted for the more detailed alternative plans presented in Chapter 3 of this volume. Rather, comparing the scenarios was intended to provide an understanding of the basic differences of alternative future development patterns and transportation system development. The evaluation did, however, capture a range of performance-related issues through 13 measurable criteria and
showed how all five scenarios would likely perform relative to one another. The evaluation and criteria are described on the following pages.

Criteria for Scenario Evaluation
A series of 13 measurable criteria were selected to evaluate and assist in comparing the scenarios. These criteria were designed to provide sketch-level estimates for the scenarios, in a more conceptual way than those used for evaluating the more detailed alternative plans in the subsequent stage of the VISION 2050 process. These criteria were developed by staff with guidance from the Commission’s Advisory Committees on Regional Land Use Planning and Regional Transportation Planning, and its Environmental Justice Task Force. Staff also considered the Guiding Statements in the Guiding the Vision booklet and public feedback received during initial visioning activities as part of the process to develop a shared long-term land use and transportation vision for the Region. The 13 criteria that were developed for evaluating and comparing the conceptual scenarios are presented in Table 2.7.

Scenario Evaluation Results
Using the 13 criteria described above, the Commission staff evaluated how each scenario would perform relative to the other scenarios. Each criterion was measured for each scenario, with the results presented in a “scenario scorecard” (presented in Figure 2.6) that allowed the scenarios to be easily compared in terms of their relative benefits, costs, and impacts. This scorecard, along with the criteria descriptions in Table 2.7, was provided to all participants at the workshops and through the online scenario exploration tool to guide their comparison of the scenarios. Evaluation results for transit service quality and traffic congestion were also provided using maps. As mentioned previously in this chapter, the quality of transit services in the Region in the year 2050 under each scenario is presented on Maps 2.4A through 2.4E. The year 2050 level of traffic congestion on the Region’s arterial streets and highways under each scenario is presented on Maps 2.5A through 2.5E, with the congestion categories defined in Table 2.8.

Evaluation results for criteria related to healthy communities showed that the scenarios that envisioned more compact, mixed-use development and investment in enhanced bicycle facilities—particularly Scenarios C, D, and E—tended to perform the best. This was reflected in the estimated number of bicycle and walking trips per day and people living in walkable areas. It was also true of annual tons of greenhouse gas emissions, although there was not substantial variation in emissions from scenario to scenario. The scenarios with more compact development, and with a focus on infill and redevelopment, also tended to preserve more farmland and undeveloped land, as less of that land would be consumed by new development.

In terms of providing equitable access for low-income and minority populations, scenarios that focused investment in transit services, particularly those serving the Region’s urban centers, tended to outperform the other scenarios. Scenarios C and E, which included rapid transit lines primarily in the Milwaukee area and TOD around those rapid transit stations, were estimated to have the most households with affordable housing and transportation costs (considered to be 45 percent or less of household

---

3 The performance graphics in the scenario scorecard show the best performing scenario under each criterion with a filled-in blue circle, the worst performing scenario with an open circle, and the remaining scenarios with circles partially filled in blue on a proportional basis relative to the best and worst performing scenarios. This method may have overstated the performance differences between scenarios for some criteria, but allowed for easily identifying the best and worst performing scenarios at a glance.
median income) as well as the highest transit service quality for minority and low-income populations.

The costs associated with each scenario also varied. Average annual transportation system investment was affected mostly by major investments in arterial streets and highways and public transit, with the scenarios that included fixed-guideway transit having significantly higher annualized capital, and operating and maintenance costs. The cost to local governments associated with supporting new development tended to be lower for those scenarios focused on more compact development, particularly those with more multifamily housing units.

<table>
<thead>
<tr>
<th>Criterion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bicycle and walking trips</td>
<td>An estimate of the total daily non-motorized trips for transportation purposes only (does not include recreational trips); varies between scenarios based on density and the level of bicycle accommodation.</td>
</tr>
<tr>
<td>Greenhouse gas emissions</td>
<td>An estimate of annual greenhouse gas emissions produced in the Region from mobile sources (cars, trucks, buses, etc.) and homes. Emissions are measured in CO₂ equivalency.</td>
</tr>
<tr>
<td>People living in walkable areas</td>
<td>An estimate of walkability (the ease by which people can walk to various destinations in an area) for residents; considers variation in household density and intersection density, with a baseline for existing walkability estimated using data from Walk Score®.</td>
</tr>
<tr>
<td>Remaining farmland and undeveloped land</td>
<td>An estimate of the land that would remain as farmland or undeveloped; varies between scenarios based on location and density of jobs and housing.</td>
</tr>
<tr>
<td>Households with affordable housing + transportation costs</td>
<td>An estimate of the number of housing units affordable at the household median income, based on combined transportation costs and housing costs (45 percent of income or less is considered affordable); varies between scenarios based on residential density and transit service quality; baseline existing data provided by the Center for Neighborhood Technology.</td>
</tr>
<tr>
<td>Transit service quality for minority and low-income populations</td>
<td>An estimate of transit service quality in areas with concentrations of minority and low-income populations in the Region; varies between scenarios based on amount, frequency, and speed of transit service in locations with concentrations of minority and low-income populations.</td>
</tr>
<tr>
<td>Cost of supporting new development to local governments</td>
<td>An estimate of select local government operating and capital costs (annualized; in year 2014 dollars; excludes education costs) for new residential development; varies between scenarios by the number of single-family and multifamily housing units; baseline existing data provided by the National Association of Home Builders.</td>
</tr>
<tr>
<td>Average annual transportation system investment</td>
<td>An estimate of operating, maintenance, and capital costs (annualized; in year 2014 dollars) of arterial streets/highways, transit, and bicycle facilities; varies between scenarios based on types and quantities of transportation infrastructure and services.</td>
</tr>
<tr>
<td>Congestion</td>
<td>An estimate of the degree of traffic congestion on arterial streets and highways, measured in centerline miles experiencing moderate, severe, or extreme congestion; congestion categories vary based on level of service, travel speed, and operating conditions.</td>
</tr>
<tr>
<td>Vehicle-miles of travel per capita</td>
<td>An estimate of the average annual vehicle-miles of travel in the Region per Region resident; varies between scenarios based on the predicted number and length of vehicle trips.</td>
</tr>
<tr>
<td>Job/housing balance</td>
<td>An estimate of the balance between the number of jobs and the number of households in communities throughout the Region; varies between scenarios based on location and density of jobs and housing.</td>
</tr>
<tr>
<td>Access to transit</td>
<td>An estimate of the number of residents with access to fixed-route transit and the number of jobs accessible by fixed-route transit; service area defined as being within 1/4 mile of a fixed-route transit stop.</td>
</tr>
<tr>
<td>Access to high-quality transit</td>
<td>An estimate of the number of residents with access to high-quality transit and the number of jobs accessible by high-quality transit; transit service is considered to be high quality if it has its own right-of-way (bus rapid transit, light rail, or commuter rail); service area defined as being within 1/2 mile of a high-quality transit stop.</td>
</tr>
</tbody>

Source: SEWRPC
Several measures were used to illustrate the anticipated mobility of Southeastern Wisconsin residents under each scenario. Scenarios A and B, which included additional traffic lanes and new facilities on the arterial street and highway system, tended to perform better in addressing traffic congestion. However, they also had higher average vehicle-miles of travel per capita due to residents driving more and having longer trip lengths. There would also be a better balance between jobs and households within the Region under the scenarios with more mixed-use, higher-density development. Regarding transit access, Scenarios B, C, D, and E would significantly increase the number of residents with access to fixed-route transit services and the number of jobs accessible by those services. Access to “high-quality” transit services—defined as transit service having its own right-of-way—would only be provided under Scenarios C, D, and E, with far more people and jobs having access under Scenarios C and E than Scenario D. This is due to the location of rapid transit lines in areas with the highest concentrations of population and employment.

Table 2.8
Freeway and Surface Arterial Traffic Congestion Levels
The level of congestion on arterial streets and highways may be summarized by the following operating conditions:

<table>
<thead>
<tr>
<th>Freeway</th>
<th>None A and B</th>
<th>Freeway operates at free-flow speed</th>
<th>No restrictions on ability to maneuver and change lanes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>None C</td>
<td>Freeway operates at free-flow speed</td>
<td>Ability to maneuver and change lanes noticeably restricted.</td>
<td></td>
</tr>
<tr>
<td>Moderate D</td>
<td>Freeway operates at 1 to 2 mph below free-flow speed</td>
<td>Ability to maneuver and change lanes more noticeably limited; reduced driver physical and psychological comfort levels.</td>
<td></td>
</tr>
<tr>
<td>Severe E</td>
<td>Freeway operates at up to 10 mph below free-flow speed</td>
<td>Virtually no ability to maneuver and change lanes. Operation at maximum capacity. No usable gaps in the traffic stream to accommodate lane changing.</td>
<td></td>
</tr>
<tr>
<td>Extreme F</td>
<td>Freeway average speeds are 20 to 30 mph or less</td>
<td>Breakdown in vehicular flow with stop-and-go, bumper-to-bumper traffic.</td>
<td></td>

2.5 THIRD ROUND OF VISION 2050 WORKSHOPS

A third round of interactive workshops, open to the general public and held throughout the Region, was conducted between September 8 and 18, 2014. The workshops were the third installment of the five rounds of public workshops held across the Region during the VISION 2050 process. The five rounds of workshops were used to provide information on, and obtain input into, the development of VISION 2050. Similar to the first two rounds, the Commission hosted one workshop in each county, with the Commission’s eight partner organizations holding individual workshops for their constituents between September 22 and October 6, 2014. A summary report of the eight partner organization workshops held in the fall of 2014 can be found in Appendix E-1. As in the previous two rounds of workshops, the Commission staff offered to hold individual workshops by request, and held one such requested workshop in the fall of 2014.\(^4\) Staff also received input through an event held on October 23, 2014, by MetroGO!

The focus of the third round of workshops was the review and comparison of a series of conceptual land use and transportation scenarios and their evaluation. Staff asked attendees a series of questions related to each concept covered under the scenarios. The questions were intended to determine what participants believed were the most important factors to consider when comparing scenarios. Attendees then had the opportunity to review, discuss, and provide feedback on each scenario within small groups. The feedback was used to develop and evaluate more detailed alternative land use and transportation plans, which are described in Chapter 3 of this volume. The workshops also involved a review of the results of the initial visioning activities conducted in the fall of 2013 and winter of 2013/2014 (summarized in Chapter 1 of this volume). Staff distributed the Guiding the Vision booklet as part of that review, which presents an initial vision for the Region’s land use and transportation system based on the key values and priorities expressed through the initial visioning activities.

Nearly 450 residents attended one of the above workshops held in the fall of 2014—about 220 people participated in the public or requested workshops, about 190 people participated in the eight partner workshops, and an additional estimated 40 people participated through the MetroGO! event.

A description of the activities at the third round of VISION 2050 workshops, along with a summary of the results of those activities, follows.

**Interactive Presentation on the Conceptual Scenarios**

The presentation at each workshop began with a brief summary of the results of the VISION 2050 process to date, referencing the Guiding the Vision booklet as the culmination of the initial visioning activities. Staff then described the purpose of the current scenario planning effort, introduced the five conceptual scenarios, and briefly reviewed the main scenario concepts and how each scenario was designed related to each concept. As staff reviewed each scenario concept, questions related to that concept were posed to participants aimed at determining what factors they considered most important when comparing scenarios. Participants responded to the questions using keypad polling devices, and a tally of responses to each question was graphically displayed on the screen in front of the room. The same questions were also asked to residents who participated through an online scenario exploration tool (described in the next section of this chapter). The results of the responses

\(^4\) The Commission staff held an individual workshop for City of Wauwatosa elected officials and staff in September 2014.
to the scenario factor questions, as well as to a series of questions concerning the characteristics of workshop attendees, can be found in Appendix E-2.

Very few respondents were supportive of low-density development outside urban centers (12 percent), while the majority preferred the Region grow more through redevelopment and infill along major transit lines (61 percent). Walworth County respondents, however, indicated a preference for encouraging redevelopment, infill, and development immediately at the edge of urban centers (50 percent).

There was a strong preference in all counties for preserving farmland, wetlands, woodlands, and wildlife habitat (85 percent) over increasing land available for development (15 percent). There was also a strong preference for locating businesses near housing and transit stops (69 percent) compared to leaving the location decision up to the business (17 percent), locating businesses near housing alone (2 percent), and locating businesses near transit stops alone (12 percent).

When asked what type of neighborhood participants would prefer, the overwhelming majority indicated one where you can walk to places like businesses, parks, and schools, with either a choice of housing types or with homes that have small private yards (88 percent), was preferable to one with homes that have large private yards (12 percent).

Respondents were also asked which bicycle or pedestrian accommodation was most important to them between sidewalks accessible to people with disabilities, off-street bicycle paths, and physically separated on-street bicycle lanes. The results were similar from county to county, with a regionwide average of 72 percent indicating that all three were important.

In terms of transportation priorities, most of the Region indicated that providing as many transportation options as possible (62 percent) was the top priority when compared to reducing congestion as much as possible (21 percent) and keeping the cost of the transportation system as low as possible (17 percent). Washington County respondents, however, indicated that reducing congestion as much as possible was more important (44 percent), compared to the other two choices (28 percent each).

The last question asked of respondents was about what was important regarding public transit. For the most part, respondents indicated that rail transit between communities of the Region in addition to improved bus service (60 percent) was more important than rail transit in the Milwaukee area in addition to improved bus service (17 percent), improved bus service alone (14 percent), and none of these (9 percent).

Exploration of the Conceptual Scenarios
Following the presentation, staff reviewed the scenario scorecard with attendees before leading them through an interactive small group activity focused on reviewing and providing feedback on each of the five scenarios. The small group activity drew upon the World Cafe Method.5 Each table or cluster of tables, with the number of tables varying based on room size and expected attendance, was devoted to one of the five scenarios. Each table included large maps depicting household growth, employment growth,

---

5 The World Café Method (www.theworldcafe.com) is a flexible, widely accepted method for effective large group conversations. It provides a setting and format that encourages participants with different perspectives to engage in productive discussions with one another and provide meaningful input on a particular topic.
transit service quality, and traffic congestion under that scenario. There was also basic information about the scenario and a form with a few questions to facilitate the group’s discussion on the scenario. Staff used the questions on the form to guide what participants considered when reviewing each scenario, and recorded the feedback from participants on the form.

The procedure for the activity involved participants gathering into small groups around each table. At their first table, staff introduced and summarized the scenario at their table, with participants then discussing the scenario for about 10 minutes. During the discussion, a staff person recorded the group’s responses. These comments could be related to a specific location, something a group member liked or disliked, or suggestions for improving upon a scenario concept during the next step in the process. After each 10-minute interval was over, staff asked everyone to move to a different table devoted to a scenario they had not yet explored. This process continued until each participant had the opportunity to explore and comment on all five scenarios. The results of the input received during this activity are summarized in the next section of the chapter.

The Commission staff made available an interactive online scenario exploration tool through October 31, 2014, for those who were unable to attend one of the fall 2014 workshops. The online tool asked the same scenario concept questions posed at the workshops, allowing users to see in real-time how well each scenario would likely match their indicated preferences. The tool had an individual page for each scenario, which included a description of the scenario, a navigable map with GIS layers that could be turned on and off, and graphics depicting the performance of the scenario relative to the other scenarios. In addition, for ease in comparing the scenarios, the tool included a page with information about all five scenarios and their evaluation. That page contained descriptions of all five scenarios, navigable images of the scenario comparison table and the scenario scorecard, and side-by-side maps illustrating household growth, employment growth, transit service quality, and traffic congestion under all five scenarios.

A total of about 960 residents participated in the exploration of the conceptual scenarios, either at a workshop or online, providing a total of over 4,300 comments related to the scenarios (includes small group, individual, and online comments). The results are discussed below, and a summary of the results can be found in Appendix E-3.

Feedback Related to the Conceptual Scenarios
Overall, it was clear that most participants at the workshops and through the online tool did not want to follow the current trends in land and transportation system development, seeing room for significant improvement. Scenario A received by far the most negative comments, while Scenario E received the most positive comments, as shown in Figure 2.7. Participants cited a number of concerns with Scenario A, including the continued decline in transit service levels and additional lower-density development. Comments in general were supportive of improving transit services and encouraging more compact development, as would occur under the four scenarios that presented alternatives to a continuation of trends.

In terms of development patterns under the scenarios, participants expressed a desire for more compact development rather than continuing the trend in lower-density development under Scenario A, particularly expressing support for the mixed-use, TOD emphasis of Scenarios C, D, and E. Some of the reasons cited for supporting a more compact development pattern

In general, participants did not want to follow current trends as in Scenario A and were supportive of improving transit services and encouraging more compact development.
included the reduced consumption of farmland, open space, and natural resources; a focus on strengthening urban areas through infill development and redevelopment; and an improved ability to walk to destinations. Figure 2.8 presents a summary of comments related to development pattern preferences.

Participants were also concerned with the housing options offered under each scenario. As illustrated in Figure 2.9, they generally preferred the range of housing options included in the more compact development scenarios like Scenario E, citing a current lack of multifamily housing in the Region and indicating that an emphasis on providing affordable housing options is important. Some participants did note that measures should be pursued to prevent gentrification that could potentially result within TODs in the Region’s urban centers. Some expressed concern that Scenario A would continue segregation for low-income populations and minority populations. Other comments expressed concern that Scenarios C and E were too focused on development in urban centers, and would not provide suitable housing choices in rural areas of the Region.

There was general agreement among participants that transit services within the Region need to be improved and expanded, with nearly all participants rejecting a future that includes a decline in transit services, as shown in Figure 2.10. Participants were particularly supportive of improving existing transit services and as well providing more transit options, and enhancing the transit system by implementing high-quality transit services like rapid transit or commuter rail. There was an acknowledgment that commuter rail services could better connect people and jobs between urban centers, citing benefits from being able to use existing freight corridors to minimize right-of-way acquisition, although some participants questioned the viability of

There were also comments urging that transit system improvements be done in a way that allows users to travel the “last mile” to their ultimate destinations.

Figure 2.11 illustrates participants’ opinions regarding traffic congestion on the arterial street and highway system under each scenario. Participants were often split when it came to whether reconstruction of the highway system should include additional traffic lanes along with new facilities (as in Scenarios A and B) or if reconstruction should be limited to modernization to achieve current safety and design standards (as in Scenarios C, D, and E). Some participants were concerned that highway expansion would encourage dependence on the personal automobile, citing that more people, particularly younger generations, would prefer options to driving to their destinations. Some comments also indicated that traffic congestion is not a significant problem in the Region. There were other participants, however, that indicated a need to limit congestion to address safety concerns related to congested roadways, and to ensure that people and goods can move efficiently within and through the Region.

The costs under the scenarios were also a concern, as shown in Figure 2.12. Participants suggested the investments made in Scenario A would not provide as high a return as those in other scenarios, and that they would not attract as many jobs or new people to the Region. Many participants pointed out that Scenario E—although it was the most favored scenario due to its multitude of transportation options and anticipated benefits related to achieving more compact development—also had significantly higher transportation system costs. Many said, in particular, implementing all of the fixed-guideway transit investments in Scenario E may be unrealistic due to the necessary investment.

levels and considerable budget constraints at the local, State, and Federal levels. They suggested finding ways to achieve increased transportation options, including some high-quality transit options, while reducing the costs of providing those options so the additional funding needed would be limited. Some pointed out that higher investment in more robust transit services can reduce personal transportation costs as more participants would be able to travel without the need of a personal automobile. Participants also cited that higher-density development, focused on infill and redevelopment, would tend to reduce the costs to local governments associated with providing services and infrastructure.

In terms of bicycle and pedestrian accommodations, Figure 2.13 shows that participants were generally supportive of improving bicycle facilities and encouraging more walkable areas. Many participants cited health benefits from encouraging more bicycle use and establishing more dense, walkable neighborhoods. Several participants expressed support for the enhanced bicycle accommodations, such as protected bike lanes, included in Scenarios C, D, and E. Some participants, however, questioned the need to invest in improved and expanded bicycle facilities, noting that the Region’s climate limits use in the winter months.

The input received on the conceptual land use and transportation scenarios was used during the next step of the VISION 2050 process, as Commission staff developed and evaluated more detailed alternative land use and transportation plans. These detailed alternative plans, which are described in the next chapter, were presented at the fourth round of VISION 2050 workshops.
